Abstract:
This paper present many research based which are useful for real time application. Animal detection is useful in prevention of animal-vehicle accidents and will increase human and wildlife safety, it will detect large animals before they enter the road and warn the driver through audio and visual signals. This also helps in saving crops in farm from animals. In this paper there is survey of different object detection techniques and for object identification as animal techniques such as object matching, edge based matching, skeleton extraction etc are there. After survey the most appropriate method is selected for animal detection and efficiency is measured. Proposed system has low false positive rate and false negative rate.

Keywords: Animal detection, Frame differencing, Template Matching

I. Introduction
Researches related to animal’s detection in image processing have been an important aspect to numerous applications. Many algorithms and methods have been developed by human being related this. Intelligent Video surveillance systems deal with the real-time monitoring of persistent and transient objects within a specific environment. The primary aim of this system is to provide an automatic interpretation of scenes and to understand and predict the actions and interactions of the observed objects based on the information acquired by video camera.

2.1 Traditional System
Traditional system requires a person who can view the system whole day. Animal detection by human eyes has been considered as the most reliable detection method if seen from the computational point of view. This is because the image structure in natural images is complex. In, it is found that a human observer is able to decide whether a briefly flashed animal scene contain an animal as fast as 150ms. In, median reaction time results indicate a speed accuracy of 92percents for reaction time of 390ms and increase to 97 percent of correctness for 570ms. Though human detection is effective and achieve satisfactory level, human eyes can easily get...
tired causing decreasing of effectiveness. Furthermore, human eyes cannot work 24 hours a day
to perform animal detection. These flaws can be curbed by applying computer vision in image
processing for animal Detection.

2.2 Intelligent Video Surveillance System
In IVS, there are basically six components. These components are listed below.

**Acquisition:** This component is basically used for acquiring the images. There is a whole array
of camera models to meet different monitoring needs. They are analogue and digital, and can be
power-operated or not. Solar cameras are also being useful in many applications.

**Transmission:** The video captured by surveillance cam-eras must be sent to the recording,
processing and viewing systems. This transmission can be done by cable (coaxial or fiber optic
cables, stranded copper wire) or by air (infrared signals, radio transmission).

**Compression:** Digitized video represents a large quantity of data to be transmitted and archived.
So, surveillance video must be compressed using codec, algorithms for reducing the amount of
data by deleting redundancies, by image or between footage frames, as well as details that cannot
be seen by a human eye.

**Processing:** Video management systems process video surveillance images, such as managing
different video flows, and viewing, recording, analyzing and searching recorded footage. There
are four major categories of video management systems, Digital Video Recorder (DVR), Hybrid
Digital Video Recorder (HDVR), Network Video Recorder (NVR), IP video surveillance
software.

**Archiving:** The video footage archiving period varies depending on surveillance needs, ranging
from a few days to a few years. There are two types of archiving devices, internal and attached.

**Display:** Video surveillance can be viewed on different devices. In small facilities, the video can
be viewed directly on the recorder, as the image is being recorded. Images are generally viewed
remotely, on a computer, or on a mobile device such as a telephone or hand held device.

Following figure shows the working of the IVS.

3. Literature Survey

3.1 Moving Object Detection Techniques
Identifying moving objects from a video sequence is a
fundamental and critical task in many computer-vision
applications. A common approach is to perform background
subtraction, which identifies moving objects from the portion of
a video frame that differs significantly from a background model
there are following challenges in developing a good background
subtraction algorithm.

- It must be robust against changes in illumination.
- It should avoid detecting non-stationary background
  objects such as moving leaves, rain, snow, and shadows
  cast by moving objects.
- Its internal background model should react quickly to
  changes in background such as starting and stopping of
  vehicles.
Thus, after doing survey of frame differencing, mean method, standard deviation and mixture of Gaussian method, we have concluded that frame differencing performs comparatively better than any other mechanism. This method works well even if there is change in background like moving leaves, falling rained.

3.2 Feature Extraction
In image processing, feature extraction is a special form of dimensionality reduction. When the input data to an algorithm is too large to be processed and it is suspected to be notoriously redundant (much data, but not much information) then the input data will be transformed into a reduced representation set of features (also named features vector). There are many algorithms and techniques for feature extraction like thresholding, blob extraction, template matching, Hough transform, and haar transform etc.

3.3 Template Matching
Template matching is a technique in digital image processing for finding small parts of an image which match a template image. To perform template matching in matlab, we have used the concept of normalized cross correlation. In signal processing, cross-correlation is a measure of similarity of two waveforms as a function of a time-lag applied to one of them. This is also known as a sliding dot product or sliding inner-product. It is commonly used for searching a long-duration signal for shorter, known feature. For image-processing applications in which the brightness of the image and template can vary due to lighting and exposure conditions, the images can be first normalized. This is typically done at every step by subtracting the mean and dividing by the standard deviation. Here we have used feature based template matching mechanism using NCC.

4. Implementation
For the implementation work, the tool selected to carry out proposed system is Matlab. As per the survey, the following Work is carried out. The steps which should be fulfilled during implementation phase are as shown in figure 2. These steps are carried out for detecting animal from the given video.

4.1 Capture Video
To capture the real time video using any webcam or IP camera, type imaqhinfo in command window to see acquisition tool information. Notice that the adaptor is Winvideo. Any webcam you connect is accessed through this adaptor. Here we are using stored video.

4.2 Moving Object Detection
Here for proposed system we have used mixture of frame differencing method for background subtraction. For implementing and setting the parameter of frame differencing method we have
referred. The results for this method are shown below.

4.3 Create the Database

To create the database, here after performing feature extraction we have made two folders. One folder contains the target images and one folder contains the template images. Now to create the target images, we have simply extracted the video frames from testing video. For example here we have used video0014.avi as our testing video, and then after we have extracted images from that video. Now, these images are stored as a target images. These images should be stored in the one folder. Some of the extracted images are shown in figure. Now, to

Create template images are stored in one folder. Now these images are further being used for comparing the images from target folder. We are using template matching mechanism to compare the target images with template images. Some of the template images are shown in figure. Template images are used further for applying.

Normalized cross correlation concept in finding animal from the frame. Here mainly we are
finding small signal from the large signal. So target database will be used to find template images. Here if template image does not match exactly with target image then also proposed scheme is such that it detects the object. So, here even if there if only nine template images still animal can be accurately detected from more than 77 frames.

4.4 Template Matching
To perform template matching in matlab, we have used the concept of normalized cross correlation. In signal processing, cross-correlation is a measure of similarity of two waveforms as a function of a time-lag applied to one of them. This is also known as a sliding dot product or sliding inner-product. It is commonly used for searching a long-duration signal for a shorter, known feature. For image-processing applications in which the brightness of the image and template can vary due to lighting and exposure conditions, the images can be first normalized. This is typically done at every step by subtracting the mean and dividing by the standard deviation.

4.5 Results and Analysis
Here we have manually checked the efficiency of the proposed system. This section describes the false positive rate and false negative rate of the system.

4.5.2 False Negative Rate
False negative rate indicates that it does not show the rectangle on the frame even if the animal is present. So, here to find the false negative rate for our implemented code we have taken 120 frames and from that 22 frames are showing Rectangle even if there is no animal. So, false negative rate for our code is 18.33%. Thus, the efficiency of the code=100-18.33= 81.67%.
5. Conclusion

Intelligent farm surveillance system refers to the video level processing techniques for identification of specific objects, in recorded videos of the farm. In our work, we have assumed video, to be a series of images and have extended the concept to identify animal from videos of the farm. Different image processing techniques have been surveyed and implemented to recognize animals in video more efficiently. Background subtraction methods like frame differencing, mixture of Gaussian and sum of absolute differences were implemented and tested on the video. Out of them frame differencing works better. After that database is generated for target and template images. At last the template matching mechanism is used for detecting animal from the video. To implement template matching, normalized cross correlation technique is used. On detection of the animal an alarm is generated as a feedback. We have observed that the above methods work well for animal detection. Hence, the false positive rate for animal detection is 13.3%; while false negative rate for animal detection is 18.33%. The proposed technique has 84.18% efficiency for animal detection.

6. Future Work

Here as matching algorithm we have used NCC (Normalized cross correlation), in future any machine learning technique like SVM or neural network can be used.
